"Blue gentian"  
Toronto

### 1. General Description

The "Blue Gentian" (Blauer Enzian) is an highspeed circuit vehicle. The carriageway is made up of 2 pieces of circular pipes  $\varnothing$  108 mm and with a center-to-center distance of 900 mm and an intervening truss. The power tracks are located under the carriageway rail: two on the left and two on the right side, which are used for the electrical power supply of the vehicles. The rail rests upon planer jacks. The rail course corresponds to an eight where a merry-go-round is placed in the left loop. The minimum rail height amounts to 0,795 m, the maximum rail height to 6,1 m, the station being located at a height of 1,00 m. In the loops the carriageway rail is inclined towards the interior up to 40 degrees Maximum. In contrast to a roller coaster, which consists of single vehicles, the passengers of the "Blue Gentain" are transported in a train of 10 single vehicles, which are coupled together. Each vehicle has a driving unit, which delivers its power to the driving rail by means of a wheel. The train runs 36 km/h on an average, the final velocity amounting to 45 km/h. Driving velocity, acceleration and braking of the train can be set individually at the driving respectively the control table. The variable velocity, the complete passage of the apparatus at maximum speed, the comparatively short transitions between the loops and the merry-go-round with its narrow and the downhill driving constantly expose the passenger to the changing centrifugal forces. The driving-respectively the control table must be controlled constantly by someone. Even the driving wind contributes to a very special and terrific feeling.

2. Technical data - "Blue Gentian" (Blauer Enzian)

Building year : *train 1980, rail 1985*

Manufacturer : Heinrich Mack GmbH & Co.

Capacity of the train: 38 persons

Number of vehicles : 1 locomotive and 9 trailers

Capacity : about 1600 persons per Hour

Rail length: 330 m

Maximum velocity : 36 km/h

Driving power: 10 motors a' 17,5 KW

Greasing the track is wear reducing concerning the wheels.  
This lubricant film is to be tested every 2 - 3 days,  
particulary at the beginnings and the ends of the curves.

Used grease: Shell Retinax A, normal fat for ball bearing.

4.2.2. Wheel housing - bearing on front - and rear axle

Use each week "Staburags N 12 M F from Klüber  
Lubrication München KG

The fat has to step out slightly.

4.2.3. Slide bearing between rear axle and the upper part of the chassis

In the first 14 days of the starting you should grease daily,  
then every 2 or 3 days or later, when it seems to be necessary.  
There should be a constant lubricant film.

Used grease: "Grafloscon A" Grafit - Haft - Schmierstoff from  
Klüber

4) Maintenance of the equipment "BLAUER ENZIAN" (see page 11)

The following parts and functions should be maintained daily or while operating or after the following statements. For maintenance the train, you should stop the train in the last curve in front of the station.

4.1) General

Daily tests:

You have to look after all rods connectors for the trains and the safety bars. Further you have to check all wheel housings and safe guards.

Worn out and noncircular wheels have to be renewed.

4.2) The following lubrication points have to be maintained as follows

4.2.1) Track in the reach of the running of the wheels

You should slightly grease the pipe of the track, to have a constant lubricant film.

### 3. Preparation for starting

Before daily operation with passengers some test runs (3 - 5) have to be done to check if the ride and the safety bars work orderly.

See point 4 - maintenance of the ride.

The opening should ensue to the Function specifications of Firma Hch. Baumüller, 8500 Nürnberg.

Before daily operation the oil in the gears has to be warm. This means, during the first 10 - 15 min. you should drive slowly to avoid foaming of the oil.

### Attention!!

Important advices for the first starting:

The running-, guide- and safety wheels have to be run in slowly.

That means, the train has to be run only half of the maximum speed for 1,5 hours.

Then the speed can be raised to the maximum within 15 minutes.

During this time (1,75 hours) a regular operation with stops and starts should be simulated, as if passengers are carried.

During this time the plastic of the wheels gets its firmness.

In order to avoid the detaching of the plastic at the wheels you have to pay attention to the advice for the first operation, otherwise the wheels could get hot.

If you have to change a single wheel you should keep 1/2 an hour's time to run in..

### Starting

Switch on the key-operated switch "releasing control". Tip the button "cancel breakdown" for a moment. Unlock the mushroomtype button "emergency stop". The lamp "emergency off" extinguishes. Operate the tail-end drives by switch S 4 "auxiliary drives". Only "auxiliary-on" lights up. Breakdowns and emergency stops must always be answered by "cancel breakdown". Now one can start by button S 6 "start". The apparatus rotates at the speed set by the potentiometer "speed-rotation". The signal lamp "operating-driving" lights up. After pushing the push button "stop" the apparatus slows at the value set by the potentiometer "retarding force". The lamp "operating braking" lights up. The drive motors are switched off, if the "rotor-voltage" is smaller than 40 V. A renewed start is not possible during the braking process. When "emergency stop" is pushed during the ride, the train slows down at an internally set maximum current value. After the key-operated switch "releasing-control" has been turned off, the drive of the apparatus is cut off the electrical power supply. This is meant for eventual emergency cut-off in case of breakdowns.

4.2.4) All wheels with antifriction bearing

About every three months you should lubricate the bearings with normal ball bearing fat.

4.2.5) Gear box

Maintenance and spare parts according to enclosed informations

V 200 EN 9.78, Drawing 5161914,

Spare parts list 1 E 5052283 of Flender Company, Bocholt

4.2.6) Safetybars and compressor

Air filter of the compressor it to be greased slightly every month with a non-resinous oil.

The safety bars must be greased monthly, if grease nipples are existing, otherwise lubricate slightly.

4.2.7) All cables, the track and other electric parts are to be tested every 3.- 4 days and defect parts have to be changed immediately.

While working on the electric parts, turn off the main switch

4.2.8) Brushholder

Are to be tested daily and defect or wornout brushes are to be changed immediatly.

The brushes should be turned absolutely after approx. 20 operating days to compensate the wearing.

4.2.9. Spare parts for electric

according to E - part list

control box drawing no 215 b,

Baumüller company, Nürnberg

- Adjustment:
1. Tighten crownnut M 36.
  2. Turn down crownnut M 36 about 1/4 turn to the next split-in hole.
  3. Fit the split in into the hole and secure it.
  4. Fix the normal nut and secure it.
  5. WHEEL ASSEMBLY HAS TO BE TURNED BY HAND !!!!!

bushing made of red brass  
Control the clearance and renew  
if necessary!

Sliding washers inside are red brass Ø 65x5 mm  
Control the wear eventually renew them.

Joint bearing GEH 90, control bearing  
clearance!

Guide- and guard wheel have a eccentric  
shaft, to adjust the distance between wheel  
and track. Minimum: 3 mm, max. 8 mm

Lateral wheel L min. 1 mm; L max. 5 mm  
Safety wheel L min. 3 mm; L max. 8 mm  
guard wheel

Sliding washers outside are red brass Ø 60x5 mm  
Control the wear, eventually renew them.

Attention: To controll different functions  
it is necessary to unload the  
axles, through lifting up the  
whole car. (with a hydraulic jack)  
In this position it's important to control also  
all bearings of the wheels because of smooth running

ATTENTION!  
The wear out of running-,  
guide- and guardwheel should  
never be more as 5 mm!
